Swapnil Landge

Ph.D. Candidate in Economics, The Graduate Center, CUNY

slandge@gradcenter.cuny.edu | https://swapnillandge.com

Research Interests

Primary: Labor Economics, Applied Microeconomics
Secondary: Intergenerational Mobility, Income Inequality, Machine Learning in Economics, Applied Microeconometrics

Education

The Graduate Center, City University of New York (CUNY)　　　　New York, NY
Ph.D. in Economics, Expected 2026
M.Phil. in Economics, Sept. 2023

University at Buffalo, SUNY　　　　Buffalo, NY
M.S. in Econometrics and Quantitative Economics, Jan. 2020

Symbiosis Institute of Operations Management, SIU Pune, India
MBA in Operations Management, Feb. 2010

Government College of Engineering, Karad, India
B.E. in Electrical Engineering, Dec. 2007

Intergenerational Transfer of Occupational Skills: A Causal AI and Machine Learning Analysis of Fathers' Skills and Children's Career Outcomes(Link)

This paper examines how Fathers' occupational skills shape their Children's career outcomes, linking nationally representative microdata from IPUMS USA (2000–2023) with detailed skill measures from O*NET. Constructs detailed (*non-clustered*, 35 skills) and aggregated (*clustered*, 5 dimensions) skill measures, analyzing outcomes across 23, 9, and 3 occupational groups.

A two-stage framework combines interpretability and predictive power. First, multinomial logistic regressions reveal strong skill–occupation alignment: children are significantly more likely to enter occupations requiring the same skill clusters as their fathers. Technical and analytical skills predict STEM and skilled manual roles, while managerial and communication skills have broad influence across cognitive and service occupations. Second, Extreme Gradient Boosting (XGBoost) models, interpreted via SHapley Additive exPlanations (SHAP), capture non-linear effects and rank skill importance. Predictive accuracy improves from 21% (23 categories) to 56% (3 categories), with a small set of cognitive, communication, and problem-solving skills emerging as consistently influential.

Findings reveal skill-specific intergenerational transmission beyond socioeconomic status, informing education and workforce policies to foster mobility through transferable and technical skills.

Working Papers

- *Intergenerational Transmission of Occupation in the USA* (Link)

  Presents a detailed empirical analysis of how occupations are transmitted from fathers to sons in the U.S., using a large dataset of 56,952 parent-child pairs from the PSID (1968–2001). Its key novelty lies in focusing on the actual occupation categories rather than occupational rankings and quantifying intergenerational persistence across the full occupational spectrum.

  The main finding is that occupational following is significantly higher both at the top (e.g., doctors, engineers) and bottom (e.g., service workers) of the socioeconomic ladder. For instance, sons of professionals have a 32.1% probability of entering the same field, while sons of service workers show a 25.8% match rate—demonstrating that inequality is perpetuated through both privilege and disadvantage via occupation-specific human capital and intangible entry barriers like soft skills.

- *Relationship between Intergenerational Mobility (IGM) and Economic Growth: Evidence from Cross-Country Data* (Link)

  This paper extends the work of Aiyar and Ebeke (2019) by incorporating updated cross-country data (GDIM 2021 and All the Ginis 2019) and refining the empirical strategy to more robustly assess the role of intergenerational mobility (IGM) in shaping the relationship between income inequality and economic growth. It contributes new insights by emphasizing intergenerational educational mobility and applying a dynamic panel model using System GMM to address endogeneity concerns.

  The central finding is that income inequality has a significantly more negative impact on economic growth in countries with low intergenerational mobility. In contrast, in societies where mobility is higher, the adverse effect of inequality is notably muted. These results underscore the importance of not just reducing income inequality, but also improving equality of opportunity through policies that enhance educational access and human capital development across generations.

Peer Reviewed Publications (R&R)

- *Intergenerational Self-Selection Model: The Influence of Fathers' and Mothers' Occupations on Children's Occupational Outcomes — Journal of Applied Economics* (Link)

  Paper presents a novel self-selection model that combines Roy's occupational choice theory with Becker and Tomes's intergenerational transmission framework, using a bivariate Fréchet distribution to model inherited skills. The key innovation is its comparative analysis of how mothers' and fathers' occupations influence sons' and daughters' career outcomes differently.

  The main findings show that sons tend to experience positive self-selection when following their father's occupation—especially in skilled, high-wage fields—whereas both sons and daughters who follow their mother's occupations in low-wage sectors like service or farming often face negative self-selection, meaning they would have earned more in alternative careers. These results highlight the gendered dynamics of occupational inheritance and the structural inefficiencies it can perpetuate in the labor market.

- *Legacy of Labor: The Impact of Parental Jobs on Children's Career Choices and Income Inequality — Journal of Applied Econometrics* (Link)

  This paper introduces a novel empirical model of occupational self-selection that integrates the Roy (1951) model with Becker and Tomes's (1979, 1986) theory of intergenerational transmission.

The key innovation is modeling innate skills using a bivariate Fréchet distribution, allowing for asymmetric, parent-influenced skill inheritance. It captures how a child's occupational choice is shaped not only by market returns but also by inherited, profession-specific abilities from parents.

The main finding reveals that a significant proportion of children from middle- and low-income backgrounds are negatively self-selected into their parents' occupations—meaning they would have been more productive and earned higher wages in higher-income jobs. Specifically, 11.5% of children from middle-income and 21.9% from low-income backgrounds fall into this category, pointing to a misallocation of talent and a mechanism by which income inequality persists across generations.
